Magnitud del problema

➤ La estenosis aórtica (EA) es la valvulopatía más prevalente en adultos de >65 años.

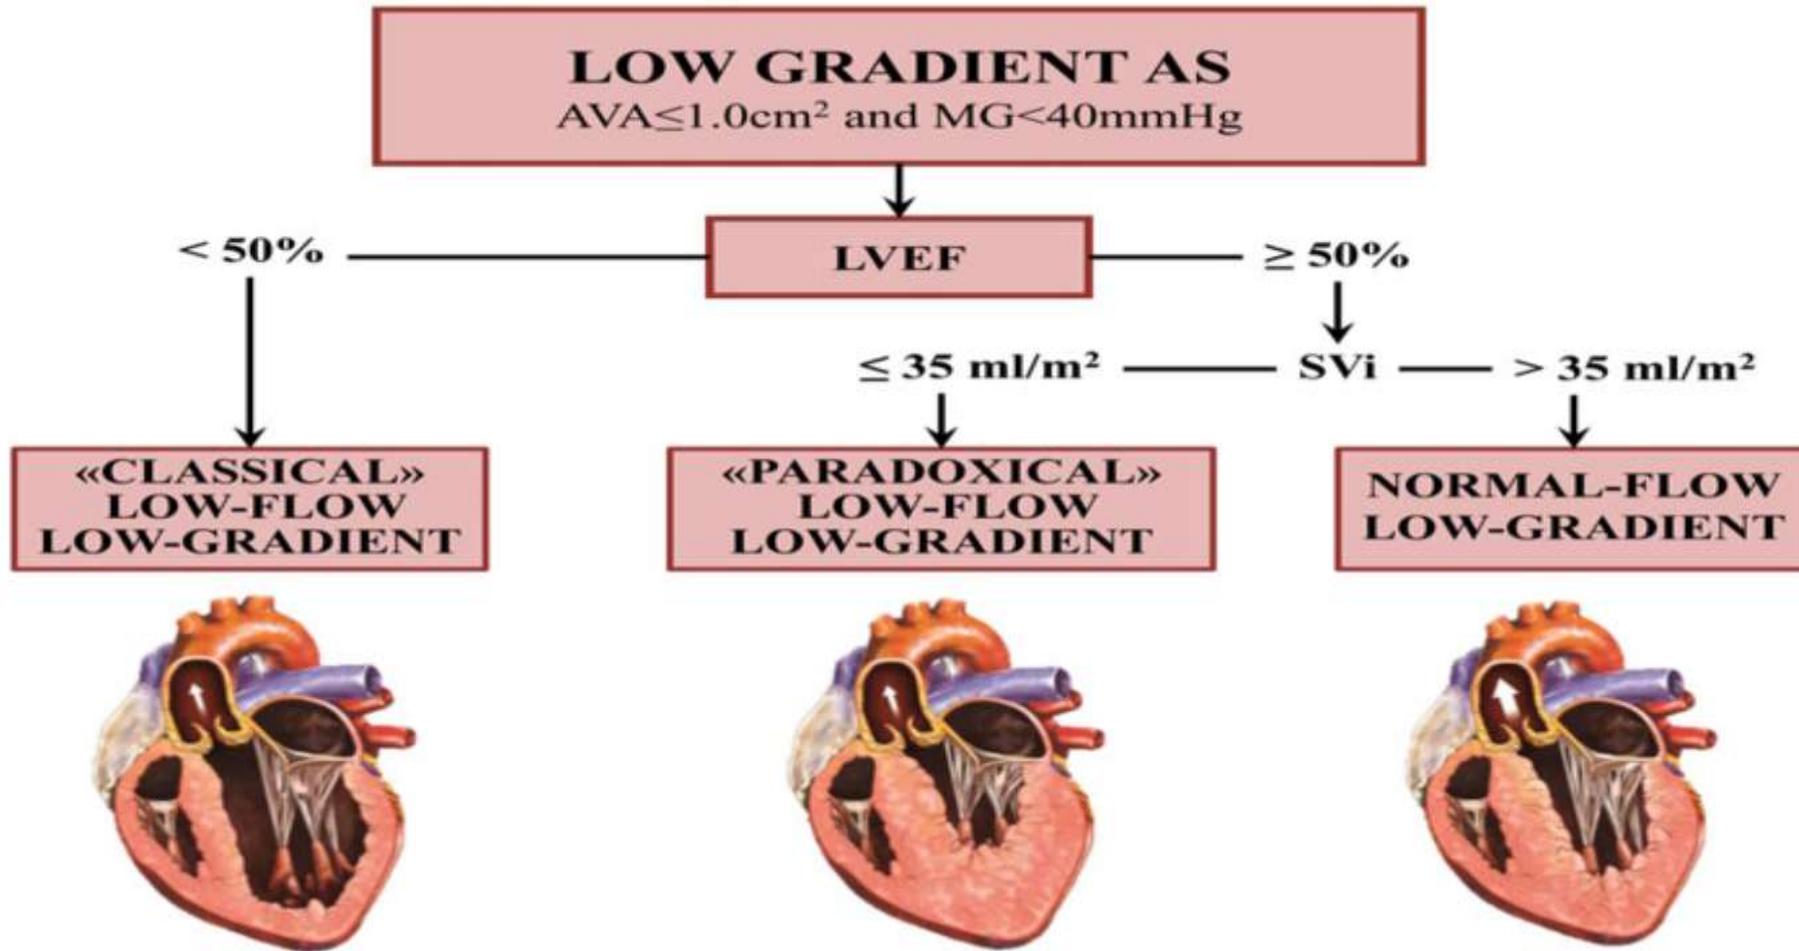

➤ El subtipo EA BG representa entre el 10–35% de los pacientes con EA severa sintomática.

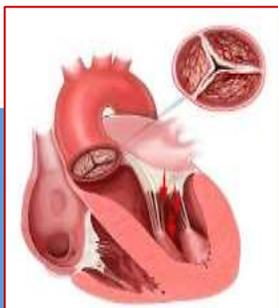

➤ Mayor prevalencia en mujeres, hipertensos e hipertrofia ventricular izquierda.

Circ Cardiovasc Interv. 2020 Jul;13(7):e008792.

El problema

Tipología de ESTENOSIS AÓRTICA

	63.5%	36.5%		
	EAo: <i>Flujo Normal Elevado Gradiente (Clásica)</i>	9.9% EAo: Flujo Normal Bajo Gradiente (FN-BG)	7% EAo: Bajo Flujo Bajo Gradiente (BF-BG "Paradójica")	19.6% EAo: Bajo Flujo Bajo Gradiente (BF-BG "Clásica")

American Journal of Medicine, Vol 130, No 3, March 2017: 253-263

Fisiopatología EAo BF-BG

Mecanismos implicados:

- Disfunción diastólica ventricular reducción del volumen sistólico
 - ✓ Hipertrofia concéntrica → menor volumen de llenado
 - ✓ Fibrosis miocárdica → menor reserva contráctil
- Disfunción sistólica ventricular con reducción vol. Sistólico
- Aumento de post-carga y de impedancia valvulo-arterial → desacoplamiento ventrículo–válvula–arteria

2

Aspectos diagnósticos

Aspectos a destacar en el Diagnóstico Diferencial

Key Points

1. Low flow, low gradient AS with preserved ejection fraction is defined as (i) AVA $<1 \text{ cm}^2$, (ii) peak velocity $<4 \text{ m/s}$, (iii) mean pressure gradient $<40 \text{ mmHg}$, and (iv) normal LVEF ($\geq 50\%$).
2. When considering low flow, low gradient AS with preserved ejection fraction, important to exclude:
 - Measurement errors (most importantly, underestimation of LVOT area and thus flow).
 - Severe hypertension during examination.
 - Inconsistency between AVA and velocity/gradient cut-offs in the range of AVAs between 0.8 and 1.0 cm^2 .
 - Clinically moderate AS (despite an AVA $< 1.0 \text{ cm}^2$) in a patient with small body size.

Helmut Baumgartner et al.

<http://dx.doi.org/10.1016/j.echo.2017.02.009> EACVI/ASE CLINICAL RECOMMENDATIONS

Diagnóstico EAo BF-BG: “Errores en la valoración de severidad”

Related to patient

- Body habitus and anatomy
- General status: postoperative, acute illness, chest disorders, COPD, etc.
- Physiology: rate, rhythm

Related to image acquisition

- Operator skill and experience
- Mistaking mitral regurgitation for AS
- Pitfalls: max velocity and mean gradient
 - Highest velocity missed due to lack of use of all windows (non-parallel intercept angle)
 - Over- or underestimation if spectral Doppler not traced appropriately
- Pitfalls: AVA by continuity equation acquisition
 - Underestimation of AVA if highest VTI or velocity not recorded
 - Difficulty measuring LVOT diameter, e.g., heavy calcification, shape of LVOT
 - Inaccurate PW sampling – leading to over- or underestimation
 - Subaortic obstruction leading to difficulty measuring LVOT or VTI
 - If patient not in sinus rhythm: 8-10 quality beats needed

Related to method of assessment

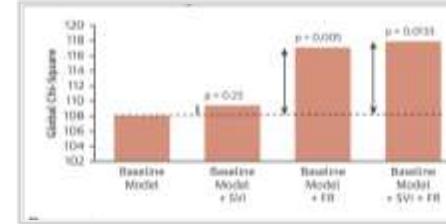

- Most parameters are flow-dependent
- DVI is least flow-dependent measure of AS severity
- Low-dose dobutamine challenge may be needed to assess contractile reserve

Related to analysis and interpretation

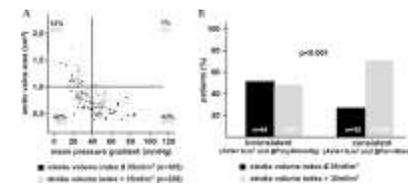

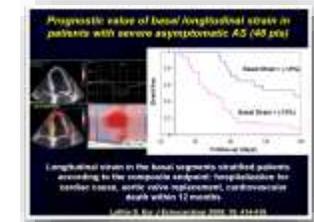

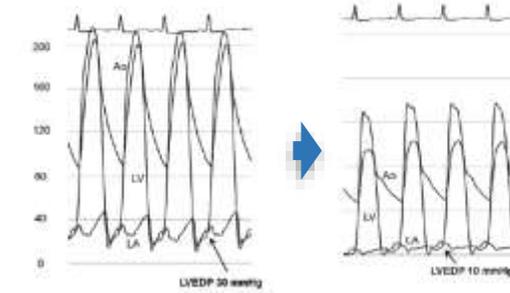

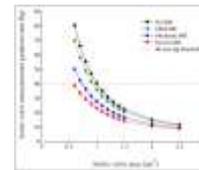

- Inter- and intra-observer error
- Learning curve

Diagnóstico EAo BF-BG: “Errores Ecocardiográficos”

- ✱ Concepto de bajo flujo
- ✱ Medición anillo
- ✱ Medición apropiada gradientes
- ✱ Insuficiencia mitral
- ✱ Hipertensión arterial
- ✱ FEVI 50% es normal en EA
- ✱ EA severa si $AVA < 1\text{cm}^2$

Parameter	Value	Normal Range
AV Ao	1.2	1.0-2.0
AV Ao	0.44	1.0-2.0

Inconsistent grading of aortic valve stenosis by current guidelines: haemodynamic studies in patients with apparently normal left ventricular function

Jon M. Altaba, María Victoria, Clara Golik, Manuel, Iñaki Pérez, Kostas, Frank-Joel Neumann, Fabrice Zanoni

Heart 2010;96:1463e1468

DIAGNÓSTICO DIFERENCIAL: Test Dobutamina

Table 4 Low dose dobutamine protocol

Starting dobutamine dose of 2.5 to 5
mcg/kg/min

Increase dose 2.5 to 5 mcg/kg/min
every 3-5 minutes

Maximum dobutamine dose of
20 mcg/kg/min

Infusion stopped when:

- 1) Maximum dobutamine dose reached (20 mcg/kg/min)
- 2) Positive result obtained
- 3) Heart rate rises 10-20 bpm over baseline or exceeds 100 bpm
- 4) Symptoms, blood pressure fall, or significant arrhythmias

Positive Result:

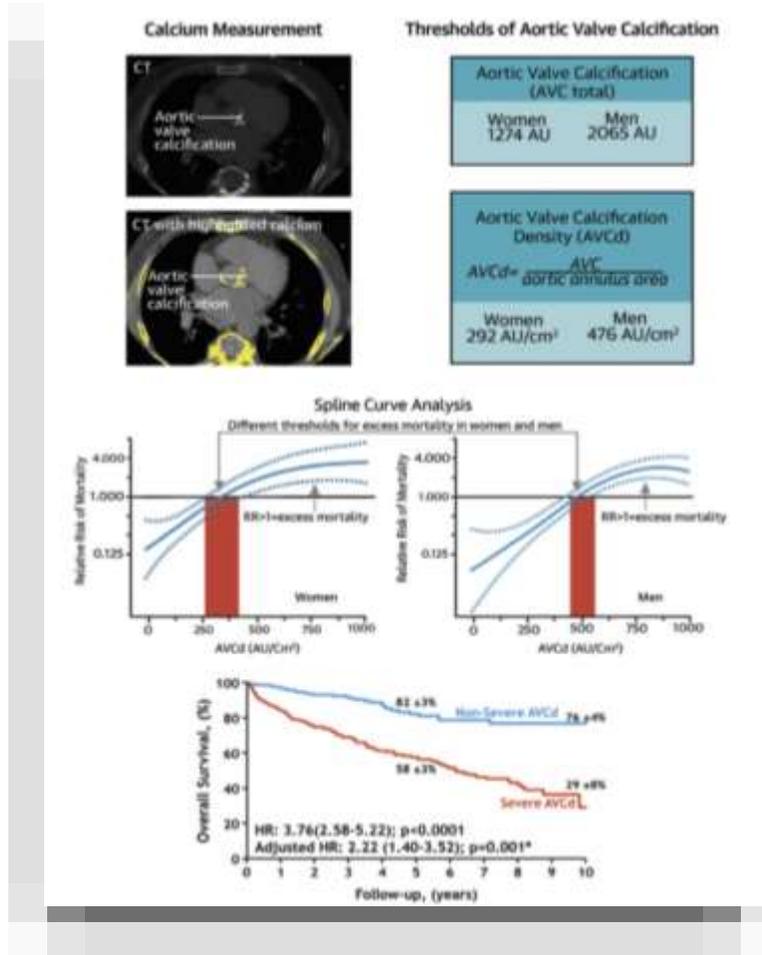

- An increase in effective AVA to a final valve area $>1.0 \text{ cm}^2$ suggests that stenosis is not severe [47].
- Severe stenosis is suggested by an AS jet velocity $\geq 4.0 \text{ m/s}$ or a mean gradient $> 30\text{-}40 \text{ mmHg}$ provided that valve area does not exceed 1.0 cm^2 at any flow rate [50,51].
- Absence of contractile reserve (failure to increase SV by $>20\%$) is a predictor of a high surgical mortality and poor long-term outcome although valve replacement may improve LV function and outcome even in this subgroup [52].

Helmut Baumgartner et al.

Guías Clínicas

Guías Clínicas 2025

Recommendations	Class ^a	Level ^b
Symptomatic patients with severe aortic stenosis		
Intervention is recommended in symptomatic patients with severe, high-gradient AS [mean gradient ≥ 40 mmHg, $V_{max} \geq 4.0$ m/s, $AVA \leq 1.0$ cm ² (or ≤ 0.6 cm ² /m ² BSA)]. ^{388,471–474}	I	B
Intervention is recommended in symptomatic patients with low-flow ($SVI \leq 35$ mL/m ²), low-gradient (< 40 mmHg) AS with reduced LVEF ($< 50\%$) after careful confirmation that AS is severe. ^{342,343,346,348,475}	I	B
Intervention should be considered in symptomatic patients with low-flow ($SVI \leq 35$ mL/m ²), low-gradient (< 40 mmHg) AS with normal LVEF ($\geq 50\%$) after careful confirmation that AS is severe. ^{c 293,348,349,476–481}	IIa	B
Asymptomatic patients with severe aortic stenosis		
Intervention is recommended in asymptomatic patients with severe AS and LVEF $< 50\%$ without another cause. ^{14,354–359}	I	B
Intervention should be considered in asymptomatic patients (confirmed by a normal exercise test, if feasible) with severe, high-gradient AS and LVEF $\geq 50\%$ as an alternative to close active surveillance, if the procedural risk is low. ^{260–263,367,368}	IIa	A
Intervention should be considered in asymptomatic patients with severe AS and LVEF $\geq 50\%$ if the procedural risk is low and one of the following parameters is present: • Very severe AS (mean gradient ≥ 60 mmHg or $V_{max} > 5.0$ m/s). ^{14,362,363,482–484} • Severe valve calcification (ideally assessed by CCT) and V_{max} progression ≥ 0.3 m/s/year. ^{303,353,364} • Markedly elevated BNP/NT-proBNP levels (more than three times age- and sex-corrected normal range, confirmed on repeated measurement without other explanation). ^{97,365} • LVEF $< 55\%$ without another cause. ^{14,354,356–359}	IIa	B
Intervention should be considered in asymptomatic patients with severe AS and a sustained fall in BP (> 20 mmHg) during exercise testing.	IIa	C
Mode of intervention		
It is recommended that AV interventions are performed in Heart Valve Centres that report their local expertise and outcome data, have on-site interventional cardiology and cardiac surgical programmes, and a structured collaborative Heart Team.	I	C
It is recommended that the mode of intervention is based on Heart Team assessment of individual clinical, anatomical, and procedural characteristics, incorporating lifetime management considerations and estimated life expectancy.	I	C
TAVI is recommended in patients ≥ 70 years of age with tricuspid AV stenosis, if the anatomy is suitable. ^{d 1–4,389–397,465,485,486}	I	A
SAVR is recommended in patients < 70 years of age, if the surgical risk is low. ^{e 413,429,487}	I	B
SAVR or TAVI are recommended for all remaining candidates for an aortic BHV according to Heart Team assessment. ^{2,4,396,397,429,488–490}	I	B
Non-transfemoral TAVI should be considered in patients who are unsuitable for surgery and transfemoral access. ^{417–423,491–498}	IIa	B
TAVI may be considered for the treatment of severe BAV stenosis in patients at increased surgical risk, if the anatomy is suitable. ^{430–432,434,499–502}	IIb	B
Balloon aortic valvotomy may be considered as a bridge to SAVR or TAVI in haemodynamically unstable patients, and (if feasible) in those with severe AS who require urgent high-risk NCS.	IIb	C

Agenda

5

Mensajes finales

Mensajes finales

- ✓ En pacientes con EAo de bajo flujo y bajo gradiente con FEVI reducida, la ecocardiografía de estrés con dobutamina (ESD) puede ayudar a distinguir entre EAo pseudo-grave y una EAo grave real en presencia de reserva de flujo (aumento del volumen sistólico $\geq 20\%$).
- ✓ La puntuación de calcio Valvular Aórtico mediante CT está fácilmente disponible y proporciona información complementaria importante en pacientes con EAo de bajo flujo y bajo gradiente, ya que se correlaciona con la gravedad hemodinámica, la progresión y los resultados clínicos. Valores de >2000 unidades Agatston (UA) en hombres y >1200 UA en mujeres indican EA grave con alta sensibilidad y especificidad ($\sim 85\%$).
- ✓ La medición de NT-PRO-BNP puede ayudarnos a sentar las bases de la necesidad terapéutica.

Mensajes finales

- ✓ La EA paradójica de bajo gradiente a pesar de la función ventricular izquierda (VI) preservada se presenta en el 20,8% de los pacientes sometidos a TAVI, y es incluso más frecuente que una EA de bajo gradiente con deterioro de la función ventricular izquierda (11,7%).
- ✓ Las tasas de mortalidad y complicaciones precoces y al año tras TAVI para la EA de bajo gradiente paradójica son bajas y comparables a las de la EA de alto gradiente.
- ✓ Por el contrario, la TAVI para la EA de bajo gradiente y deterioro de la función ventricular izquierda se asocia con una mortalidad al año y una tasa de MACCE significativamente mayores.
- ✓ El pronóstico en estos diferentes grupos de EAo está muy relacionado con las características basales y comorbilidades de los mismos.

Mensajes finales

- ✓ El reemplazo Valvular Ao. reduce la mortalidad en pacientes con EAo de cualquier tipo Vs el Tto. Conservador
- ✓ Los pacientes con EAo de BG-FN parecen tener un mayor riesgo de re-hospitalización por insuficiencia cardíaca al año, en comparación con los pacientes con EA HG.
- ✓ Un gradiente bajo parece correlacionarse con peores resultados en comparación con EA HG. Especialmente por debajo de 20 mmHg.
- ✓ Es importante incorporar patrones de gradiente de flujo en la evaluación de los candidatos a TAVR, y uso de multimodalidad de DG por imagen (ECO, CT), y NT-proBNP para sentar la indicación y el momento adecuado de la terapéutica.

Mensajes finales

- High-gradient AS [mean gradient ≥ 40 mmHg, $V_{max} \geq 4.0$ m/s, $AVA \leq 1$ cm² (or ≤ 0.6 cm² /m²)] is considered severe irrespective of LV function and flow conditions.

Discordant criteria:

- Low-flow, low-gradient AS with reduced LVEF (mean gradient ≥ 35 mL/m² , LVEF $\geq 50\%$).
- Discordant high-gradient AS (mean gradient ≥ 40 mmHg, $AVA > 1$ cm²).

Patients with discordant normal-flow, low-gradient AS usually have moderate stenosis.293–295

Discordant high-gradient AS (mean gradient ≥ 40 mmHg, $AVA > 1$ cm²) is considered severe if not caused by a reversible high-flow status.296–298

In patients with low-flow, low-gradient AS with reduced LVEF, dobutamine stress echocardiography (DSE) can help to discriminate between pseudo-severe and true severe AS in the presence of flow reserve (increase in stroke volume of $\geq 20\%$).289,299

Cardiac computed tomography calcium AV scoring is readily available and provides important adjunctive information in patients with low-flow, low-gradient AS because it correlates with haemodynamic severity, progression, and clinical outcomes.300,301

Values of >2000 Agatston units (AU) in men and >1200 AU in women indicate severe AS with high sensitivity and specificity ($\sim 85\%$).302,303 While higher thresholds (men >3000 AU, women >1600 AU) are very specific, severe AS becomes unlikely in patients with calcium AV scoring of

Estenosis aórtica: cuándo intervenir y cómo elegir entre TAVI y SAVR

Pacientes sintomáticos con estenosis aórtica grave de alto gradiente (gradiente medio ≥ 40 mmHg, **V_{max} $\geq 4,0$ m/s, área valvular $\leq 1,0$ cm² o $\leq 0,6$ cm²/m²) deben ser intervenidos. También se recomienda intervenir en **bajo flujo-bajo gradiente** (SVi ≤ 35 mL/m²) con **FEVI $< 50\%$** , tras confirmar severidad; con **FEVI $\geq 50\%$** , la intervención “debería considerarse” si se confirma AS grave.**

Pacientes asintomáticos: se recomienda intervenir si **FEVI $< 50\%$** sin otra causa. Además, **debería considerarse** intervenir (como alternativa a vigilancia activa estrecha) cuando el riesgo procedimental sea bajo y exista **AS de muy alta gravedad** (gradiente ≥ 60 mmHg o V_{max} $> 5,0$ m/s), **calcificación severa con con progresión $\geq 0,3$ m/s/año, biomarcadores muy elevados** (BNP/NT-proBNP $> 3\times$ del límite ajustado por por edad/sexo, confirmados) o **FEVI $< 55\%$** sin otra causa. Estas recomendaciones refinan el manejo de asintomáticos con riesgo anatómico o biológico alto.

Elección del modo de intervención: la **figura 9** resume factores clínicos, anatómicos y de manejo a lo largo de de la vida. En general, **TAVI es el tratamiento de elección** en **≥ 70 años** con válvula tricúspide y anatomía adecuada por acceso transfemoral; **SAVR** es preferible si **< 70 años** con bajo riesgo quirúrgico. Para el resto de de candidatos a **bioprótesis**, el Heart Team seleccionará TAVI o SAVR según riesgo, anatomía, expectativas de durabilidad y preferencias del paciente. La **TAVI no transfemoral** debe considerarse cuando no son factibles cirugía ni acceso transfemoral. En **válvula bicúspide**, TAVI puede considerarse si el riesgo quirúrgico es mayor mayor y la anatomía es adecuada.

Guías Clínicas 2021

Intervention is indicated in¹

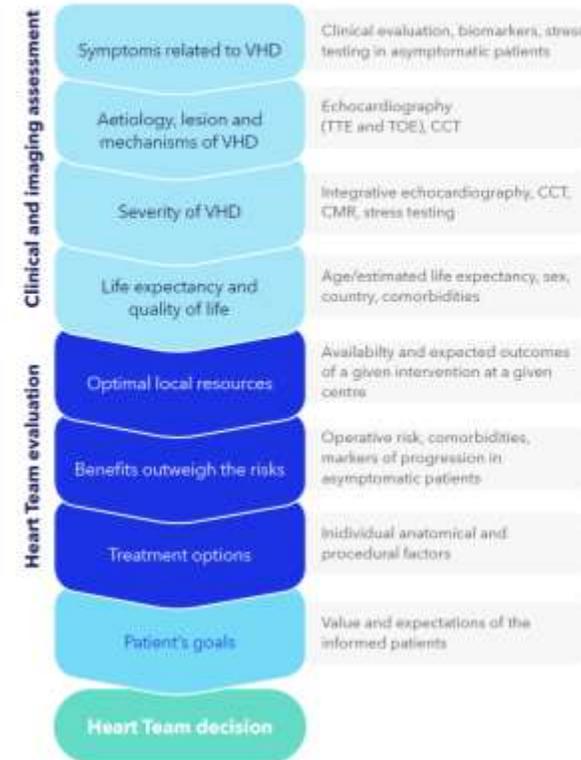

Patients with SYMPTOMATIC Aortic Stenosis	Class ^a	Level ^b
Severe, high-gradient aortic stenosis (mean gradient ≥ 40 mmHg, peak velocity ≥ 4.0 m/s, and valve area ≤ 1.0 cm ² (or ≤ 0.6 cm ² /m ²)).	I	B
Severe low-flow (SVI ≤ 35 mL/m ²), low-gradient (<40 mmHg) aortic stenosis with reduced ejection fraction (<50%), AND evidence of flow (contractile) reserve.	I	B

Patients with ASYMPTOMATIC Severe Aortic Stenosis	Class ^a	Level ^b
Severe aortic stenosis and systolic LV dysfunction (LVEF <50%) without another cause.	I	B
Severe aortic stenosis AND demonstrable symptoms on exercise testing.	I	C

Choice of intervention¹

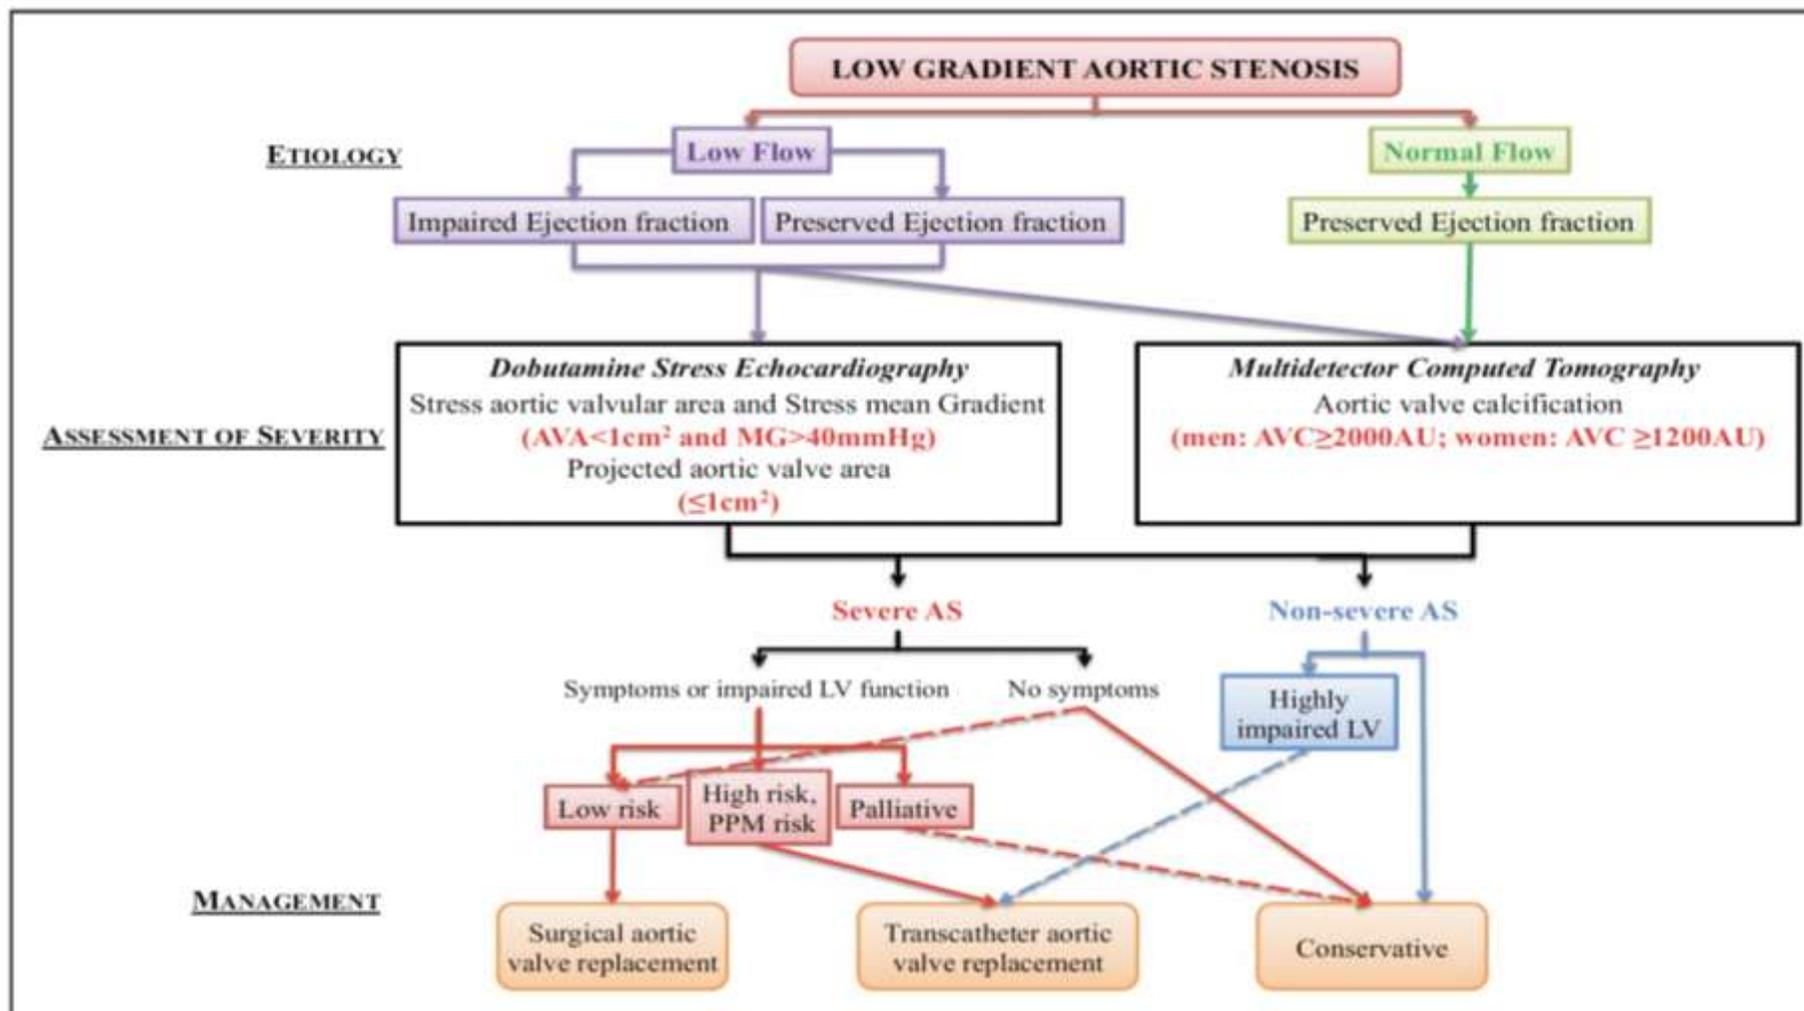

Patient-centred evaluation for intervention¹

Key considerations¹

- Lifetime management**
 "... intervention should be carefully considered by the Heart Team for all patients, accounting for individual age and estimated life expectancy, comorbidities, anatomical and procedural characteristics..."
- Early intervention**
 "Symptomatic severe aortic stenosis has dismal prognosis and early intervention is strongly recommended in all patients."
- Patient informed-decision**
 "The Heart Team recommendation should be discussed with the patient who can then make an informed treatment choice."
- Heart Valve Centre concept**
 "The main purpose of Heart Valve Centres as centres of excellence in the treatment of VHD is to deliver optimal quality of care with a patient-centred approach."

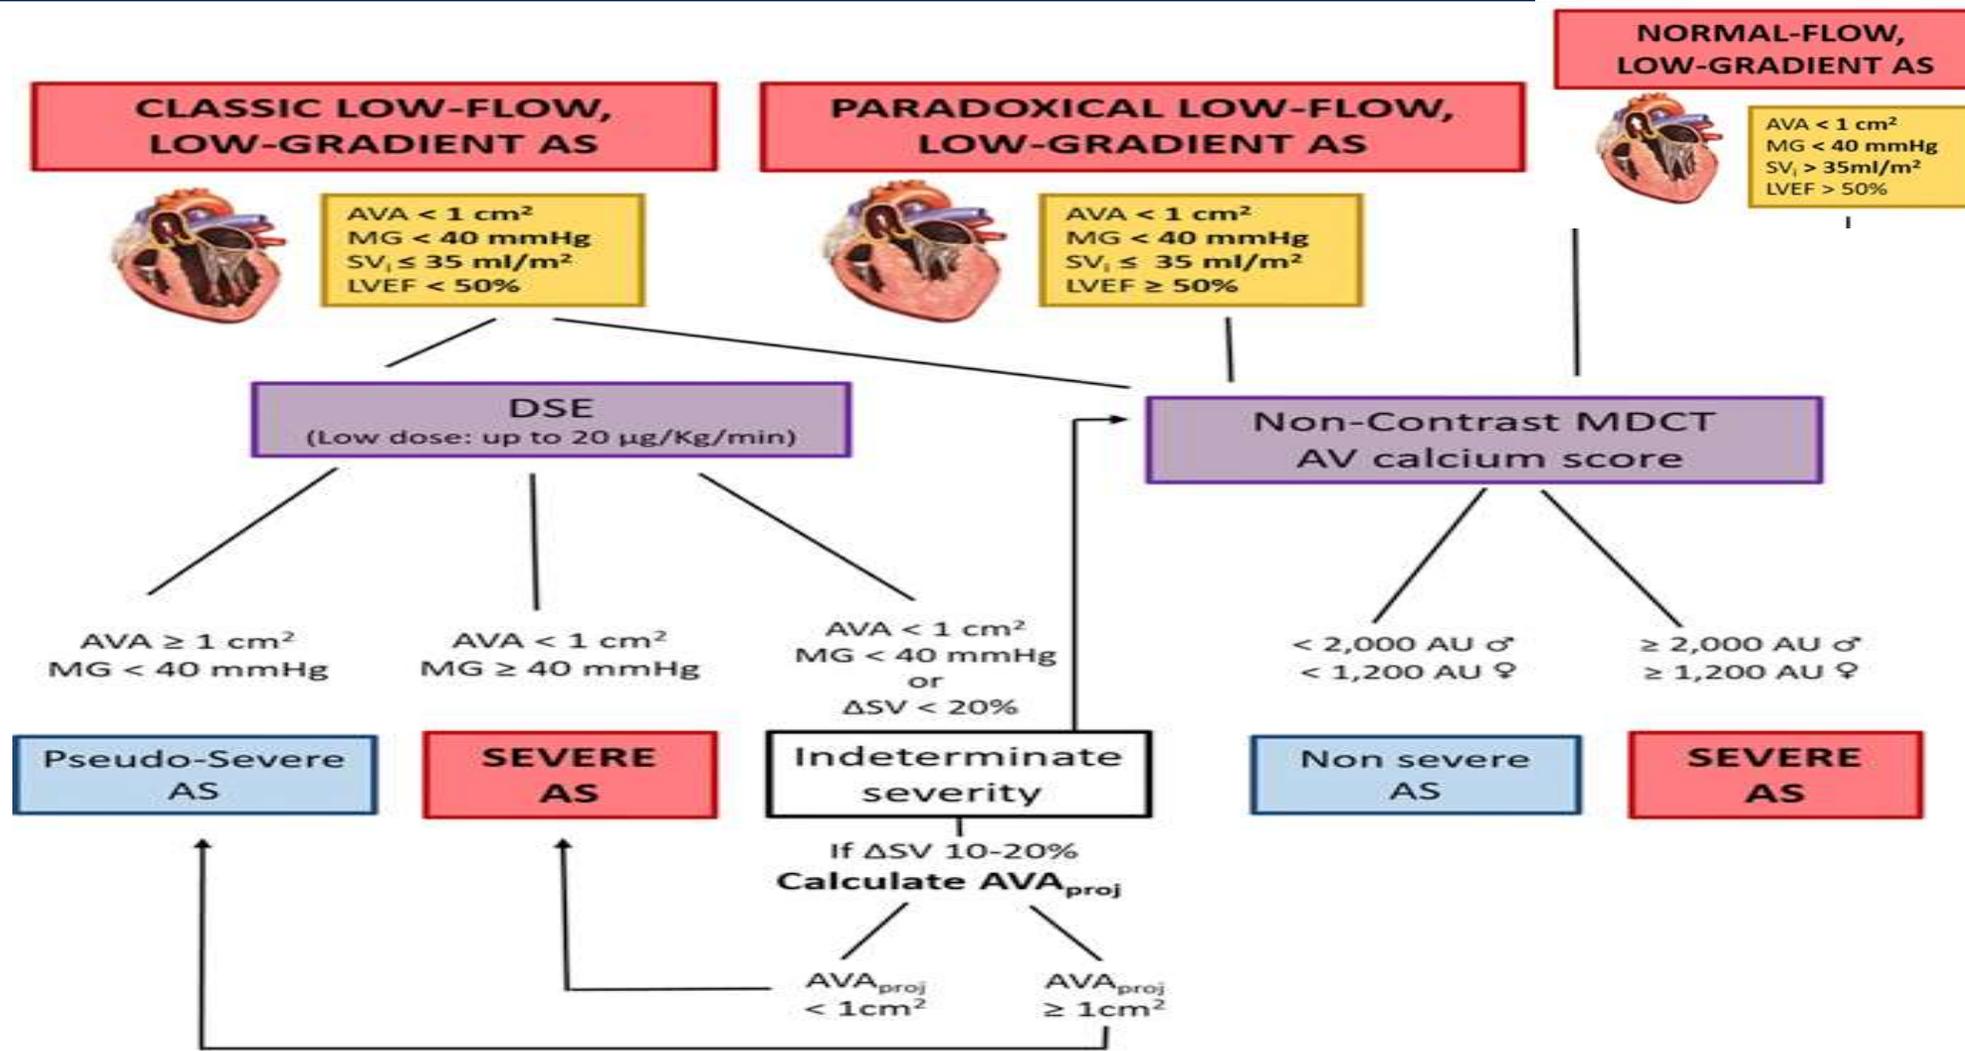

FIGURE 2 Proposed Algorithm for Evaluation of NFLG Severe AS

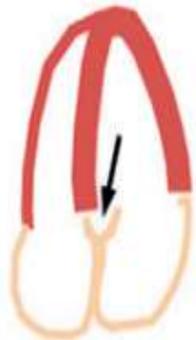

DIAGNÓSTICO DIFERENCIAL: PSEUDO SEVERA

DIAGNÓSTICO DIFERENCIAL: PSEUDO SEVERA

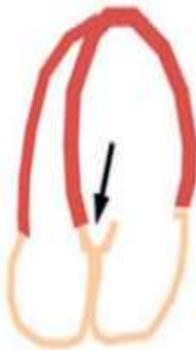

DIAGNÓSTICO DIFERENCIAL: PSEUDO SEVERA

**“paradoxical”
LF LG AS**
PGmean <40 mmHg
LVEF ≥50%

**low flow
low gradient
preserved EF**
Exclude reasons for AVA - PG discordance (see above)
small LV cavity, LVH
reduced LV longitudinal function
myocardial fibrosis
art. hypertension, older age, female
worse prognosis (compared to NF HG AS)

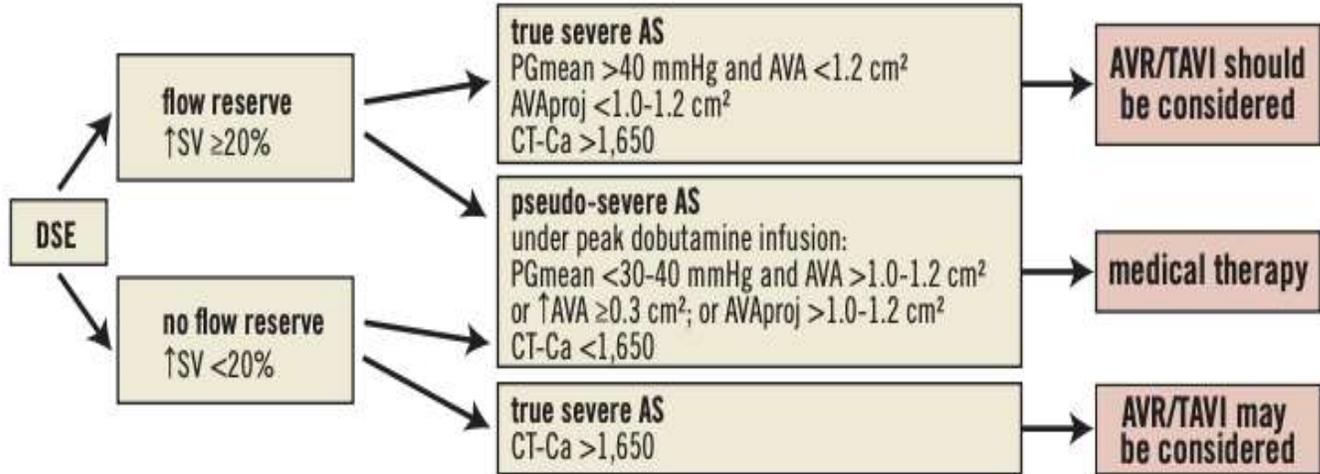

classical LF LG AS
PGmean <40 mmHg
LVEF <40%

**low flow
low gradient
reduced EF**
enlarged LV
impaired myocardial contractility
worst prognosis

Carefully exclude:
– measurement errors (in particular underestimation of LVOT area and flow rate)
– small BSA
– consider inconsistency of cut-offs for AVA and PG

CT-Ca >1,650
DSE? (needs to be validated)

AVR/TAVI should be considered

DEFINICIÓN ESTENOSIS AÓRTICA BG

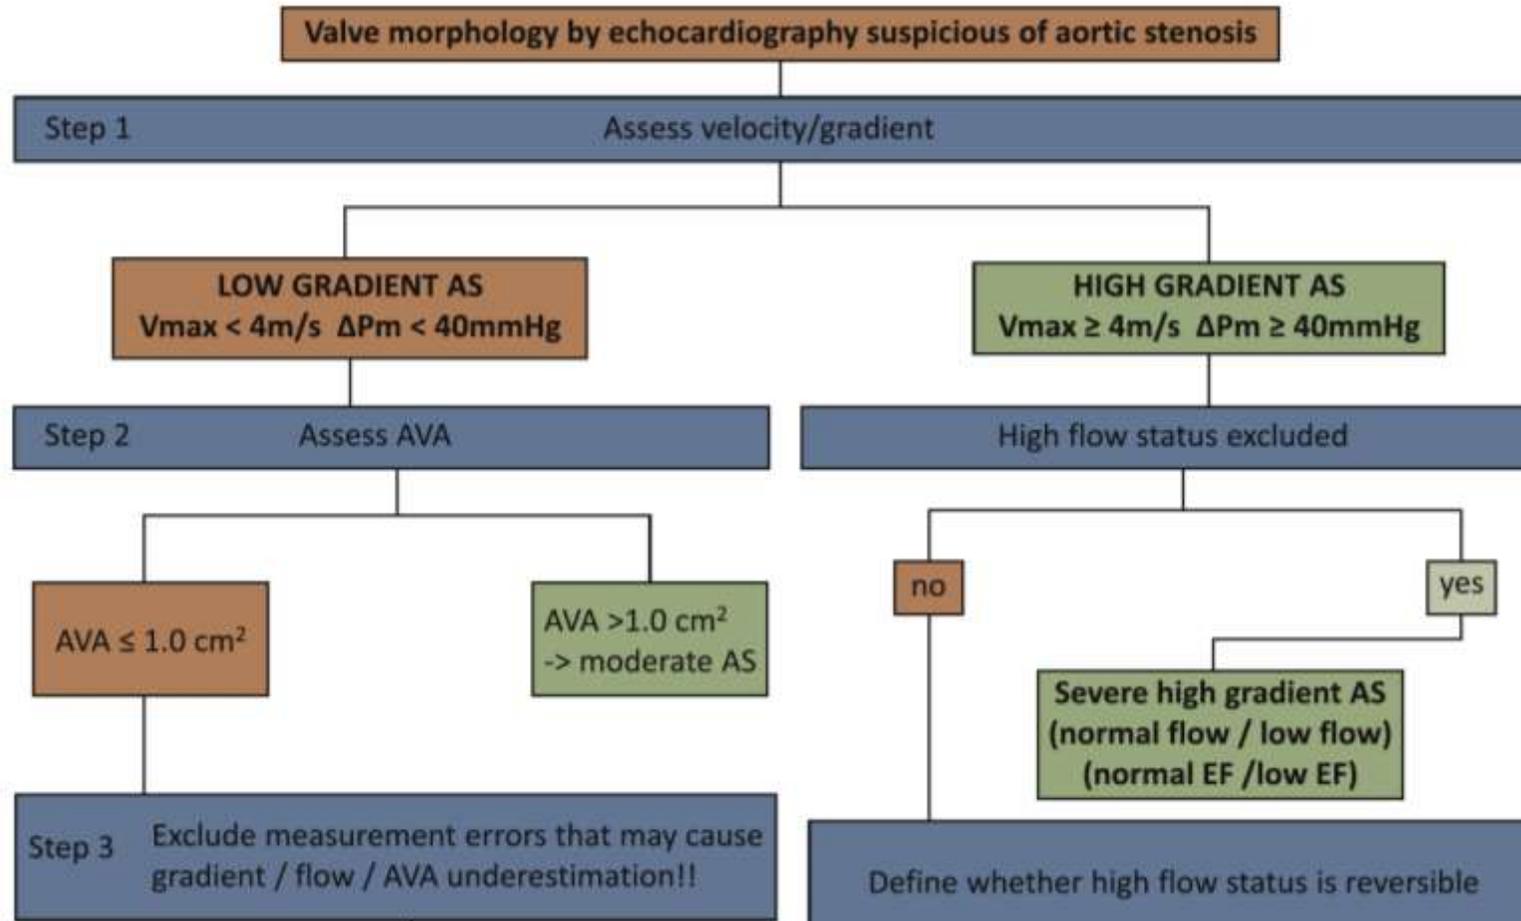

➤ La estenosis aórtica de bajo gradiente (EA-BG) se caracteriza por:

- **Área valvular $<1 \text{ cm}^2$ (indexada $<0.6 \text{ cm}^2/\text{m}^2$)***
($<0.5 \text{ cm}^2/\text{m}^2$ SI $\text{IMC} > 30 \text{ kg}/\text{m}^2$)
- **Gradiente medio $<40 \text{ mmHg}$ ***
- **VTI TSVI / VTI Vao $<0,25$**

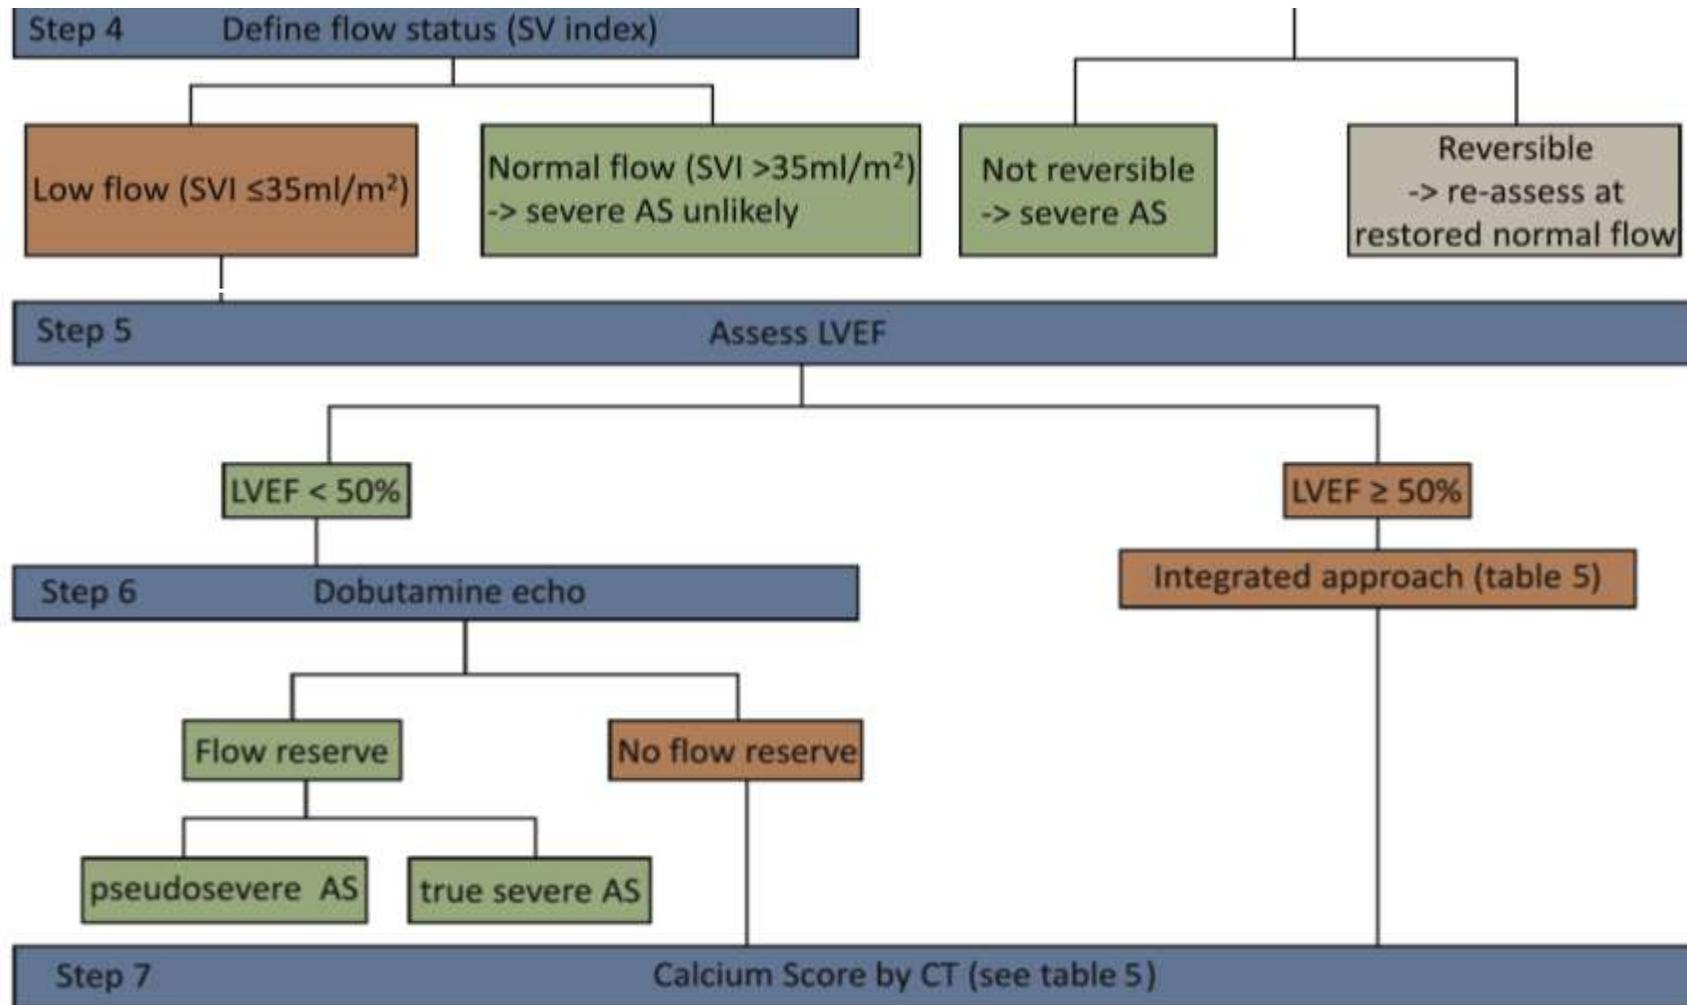

*Tras excluir errores medición

- ✓ Registro gradientes transvalvulares subóptimo
 - Valoración desde varias ventanas: apical, supraesternal y paraesternal derecho
- ✓ Confirmar situación de bajo flujo
- ✓ Infraestimación diámetro tracto salida V.Izq
 - Comprobar métodos 3D, ETE, TAC

RESULTADOS TAVI

Table 1 LFLG AS with reduced LVEF (EF < 50%)—comparison between AVR and OMT

	Population of interest (LFLG AS with reduced LVEF)	Type of AVR	AVR vs OMT HR for death at long-term follow-up
Sato et al. [17] ^a	86	TAVI and SAVR	HR 0.32 [6, 6] $p < 0,001$
Tribouilloy et al. [18]	81	SAVR	HR 0.16 to 5.21 varying with time [0.12–3.16 to 0.21–8.50], $p < 0.00026^b$
Monin et al. [19]	136 pt	SAVR	HR 0.3 (p 0,001)
Herrmann et al. [20]	42 pt (considering only inoperable true severe LFLG AS with low EF, cohort B)	TAVI	HR 0.43; 95% CI [0.19–0.98] $P = 0.04$
Clavel et al. [21]	101 pt	TAVI and SAVR	HR 0.57 [0.40 to 0.82] $P = 0.02$

RESULTADOS TAVI: Reserva contráctil no predictor

FIGURE 1 Clinical Events at 2-Year Follow-Up

Transcatheter Aortic Valve Replacement
in Patients With Low-Flow,
Low-Gradient Aortic Stenosis
The TOPAS-TAVI Registry

Patients at risk:

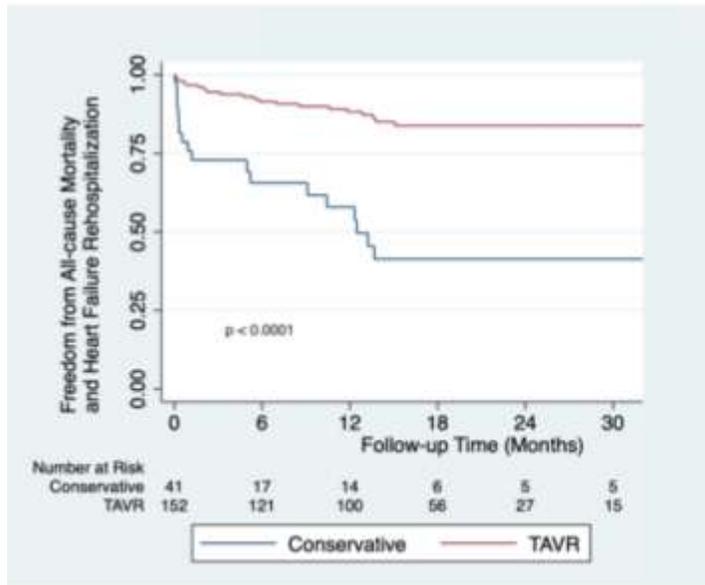

With contractile reserve	86	65	63	49	45
Without contractile reserve	107	87	72	55	46

- Mortality rates were 3.8%, 20.1%, and 32.3% at 30 days, 1 year, and 2 years, respectively.
- The absence of contractile reserve at baseline DSE was not associated with any negative effect on clinical outcomes or LVEF changes at follow-up.

Transcatheter Valve Therapy (TVT) Registry Subcohort:
TAVI procedures using Evolut valves
(June 2015-December 2022)

Excluded patients with:

- Valves other than Evolut R, PRO, PRO+, FX.
- Primary procedure indication not AS.
- Bicuspid AV.
- Previous BAV, TAVI, or SAVR.
- Procedures not eligible for 1 year follow-up.
- No implanted TAVI (only procedure attempted).

Excluded patients if confirmed with:

- Age <18 years or >105 years.
- LVEF <10% or >90%.
- AVA <0.3 cm² or >1.0 cm².
- AV peak velocity <2.0 m/sec or >7.0 m/sec.
- AV MG <10 mmHg or >120 mmHg.
- AV MG at baseline missing.

ALGORITMO MANEJO EAO BF-BG

INDICACIONES DE TRATAMIENTO

EAO BF-BG clásica

FEVI < 50% + VSi < 35 ml/m²

Intervention is recommended in symptomatic patients with low-flow ($SVi \leq 35 \text{ mL/m}^2$), low-gradient ($< 40 \text{ mmHg}$) AS with reduced LVEF ($< 50\%$) after careful confirmation that AS is severe.^{342,345,346,348,475}

I

B

EAO BF-BG paradójica

FEVI > 50% + VSi < 35 ml/m²

Intervention should be considered in symptomatic patients with low-flow ($SVi \leq 35 \text{ mL/m}^2$), low-gradient ($< 40 \text{ mmHg}$) AS with normal LVEF ($\geq 50\%$) after careful confirmation that AS is severe.^{c 293,348,349,476-481}

IIa

B

EAO flujo N-BG paradójica

FEVI > 50% + VSi > 35 ml/m²

- Prognosis of these patients is similar to that of moderate AS
- Surveillance is recommended
